Title: **Procedure Guidelines:
NASAL CANNULA
CAPNOGRPAHY**

Division: 17
Article: 2.23
Revised: October 2014
Pages: 4

NASAL CANNULA CAPNOGRPAHY APPLICATIONS FOR SPONTANEOUSLY BREATHING PATIENTS (Procedure Guideline)

SCOPE OF PRACTICE

All AEMTs and Paramedics shall operate within their authorized Scope of Practice as limited to those skills and medication approved for use by the Physician Medical Director and Physician Task Force on Pre-Hospital Care as approved and authorized by the Wyoming Board of Medicine.

SCOPE OF PRACTICE: Advanced EMTs and Paramedics

NO VOICE ORDER REQUIRED

INDICATIONS:

Nasal cannula capnography (NCC) answers need for noninvasive measurement of partial pressure of carbon dioxide (CO₂) in exhaled breath. Capnography represents CO₂ concentration over time relationship as CO₂ waveform. NCC placement should not to interfere with dealing with primary life threats or other primary treatment strategies.

In spontaneously breathing, nonintubated patients NCC can be used for:

- performing rapid assessment of critically ill or seizing patients
- determining response to treatment in acute respiratory distress
- determining adequacy of ventilation in obtunded or unconscious patients
- providing indicator for acid-base disorders
- providing additional data for patients with sepsis or septic shock
- providing low flow oxygen therapy

CONTRAINDICATIONS:

NCC therapy may be contraindicated for:

- Patients with nasal blockage
- Patients with facial injuries precluding the use of a cannula

- Patients who will not tolerate placement of nasal cannula

PROCEDURE:

1. Assemble EtCO₂ Sampling Nasal Cannula, O₂ source, Zoll X series cardiac monitor.
2. Attach EtCO₂ Sampling Nasal Cannula to O₂ source and set to desired flow rate.
3. Place EtCO₂ Sampling Nasal Cannula on patient
4. Attach sampling tube to cardiac monitor CO₂ intake and activate sampling mode by pressing Zoll X series monitor's CO₂ quick access key.
 - a. **Please note:** The Zoll X series has a typical system response time of 2.9 seconds before capnographic waveforms will present with rated accuracy.
5. Note reading and waveform(s).
6. Document procedure, numeric values and attach file to electronic patient care report.
7. Monitor patient's O₂ saturation, breath sounds, chest wall movement, respiratory rate, and capnography.

GUIDELINES:

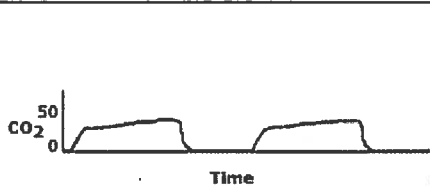

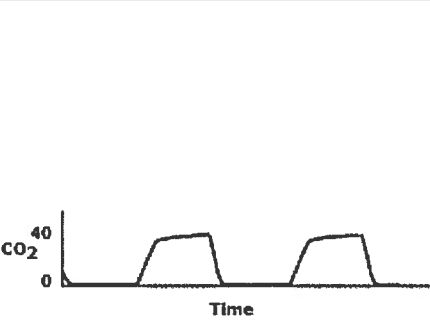

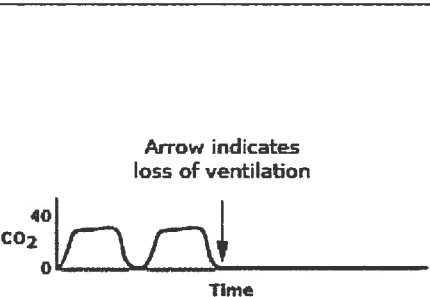

NCC can be used to assess a wide range of patients. Capnography provides reliable readings in low perfusion states.

- **NCC can be used with actively seizing patients** and is not confounded by muscle activity or movement artifact. Providers can use capnographic data to distinguish among seizing patients who are apneic, ineffectively ventilated, or effectively ventilated.
- **NCC allows providers dynamic real-time monitoring of ventilatory status in patients with acute respiratory distress** from any cause, including: bronchiolitis, croup, asthma, cystic fibrosis, heart failure, and chronic obstructive pulmonary disease.
 - a. Increasing EtCO₂ indicates worsening ventilatory status despite treatment
 - b. Stable or improving EtCO₂ indicates effective treatment
- **NCC helps differentiate between obtunded or unconscious patients with effective ventilation and those with ineffective ventilation.** Conditions that may impair ventilator function alcohol intoxication, intentional or unintentional drug overdose, and postictal conditions (especially those complicated by benzodiazepine administration).
- **NCC provides data for acid-base disturbances and can help guide treatment plan.**
- **NCC can provide another data-stream for recognizing septic patients.** In addition to standard sepsis alert criteria (e.g. high-risk patients with known/suspected infection, temperature < 36°C or > 38°C, increased pulse and respiratory rate in combination with systolic BP < 90 mm/Hg), patients may present with decreased ET/CO₂ levels.¹
